

VOXTRACE

AI Trust Infrastructure for Voice & Digital Evidence

Detect. Explain. Verify. Preserve.

From hackathon project to startup pitch — product, trust score,
use cases, business model, and revenue plan

1. How VOXTRACE & the Evidence Passport Work

VOXTRACE analyses a voice sample to detect whether it is AI-generated / cloned or a genuine human recording, and produces a verifiable trust output for each sample.

Core flow

- Detect the voice — verify if it is AI-generated or real.
- Preserve the evidence — anchor the result so it cannot be tampered with.
- Two input modes: **Live call** and **Recorded call** — sample text is spoken/played and verified against expected voice patterns.

Sample text / voice matching

To interview or verify the caller, a sample phrase is used and compared against known voice patterns to determine authenticity, along with a confidence score.

2. Sales / Tech Opportunity — B2B

Target buyers: Banks / fintechs, BPOs and call centres, HR / recruitment platforms, and any enterprise that needs to verify a caller's identity is real (not a deepfake) before trusting a voice interaction.

Customer problem

- Voice-cloning fraud is rising — CEO-voice scams, fake vendor calls, impersonation of employees/customers.
 - Enterprises need a way to confirm a call is authentic before acting on it.
-

3. Sales Unique Selling Point (USP) — 'Trust Score'

Every analysed sample gets a VOXTRACE Trust Score: a single explainable number (plus supporting indicators) that a compliance officer or ops team can act on instantly, instead of interpreting raw model output.

Example

```
VOXTRACE TRUST SCORE
-----
Score: 92 / 100
Verdict: Likely Genuine
Confidence: High
Flag: None
-----
■ High-risk indicators shown
only when score is low
```

Why this matters: non-technical decision makers (e.g. a CEO approving a wire transfer) can trust a single score rather than needing to interpret a raw ML output.

4. Use Case Deep-Dive — 'Verify the CEO'

Before acting on a high-stakes instruction received by voice (e.g. an urgent fund transfer 'from the CEO'), the call is run through VOXTRACE. A low trust score is the trigger to stop and verify through a second channel before money or data moves.

5. Third Use Case — Recruitment / Interviews

Recruiters and HR platforms can verify that the person on a remote interview call is a real, live human and not a synthetic voice or a proxy candidate reading pre-recorded / AI-cloned answers.

6. For an Actual Startup / Business

Framing VOXTRACE as an infrastructure layer (a 'trust layer') rather than a single point-tool broadens the addressable market beyond one use case.

Business Model 1 — Freemium

Free tier for individuals / low-volume checks; paid tiers unlock volume, API access and enterprise features.

Model 2

Per-verification pricing — pay for each call/sample verified, suited to lower-volume or occasional users.

Model 3

Flat monthly plans for predictable enterprise usage.

7. Main Revenue Source — B2B

The core, sustainable revenue is expected to come from B2B contracts (banks, BPOs, enterprises) rather than individual consumers, since businesses have the compliance budget and the acute fraud-risk exposure.

8. Subscription + API Revenue

A base subscription covers dashboard access and a monthly quota; additional usage is billed via the API, so revenue scales with actual call volume.

9. Hybrid Model — Recommended

Subscription (base access) + Usage-based API billing + Enterprise contracts is identified as the strongest combination: predictable base revenue, upside from volume, and large deal sizes from enterprise clients.

10. Future Product Line — Voice Authenticity Suite

Beyond fraud-call detection, the same detection engine can extend into a broader authenticity product line — e.g. verifying voice notes, podcasts, evidence recordings, and other audio content.

11. Authenticity Infrastructure

Longer-term positioning: VOXTRACE as the underlying 'authenticity infrastructure' other products and platforms plug into, rather than a single standalone app.

12. Tokenised / Usage-Based Pricing (USP)

Pricing keyed to verification volume / tokens used, so cost scales directly with the customer's actual usage of the detection engine.

13. From Hackathon Version to Startup Version

The existing hackathon build (AI Voice Clone Detection + Blockchain + Forensics) is reframed and repositioned as the seed of a real company, rather than rebuilt from scratch.

14. Revenue — Simple Illustrative Example

A hypothetical, illustrative revenue model to show how different customer tiers could stack up (this is **illustrative math, not a forecast**):

Segment	Volume	Price / month	Monthly Revenue
Small customers	100	■5,000	■5,00,000
Business customers	20	■25,000	■5,00,000
Enterprise contracts	5	■1,00,000	■5,00,000

Total hypothetical revenue: ■15 lakh / month

But this is illustrative math, not a forecast. Real revenue depends on customer acquisition, detection quality, infrastructure costs, sales cycle, and pricing validation.

15. Additional Revenue Source — White-Label / API Licensing

Suppose an existing Indian cybersecurity company already sells security software to its own customers. Instead of competing with them, VOXTRACE licenses its detection engine to them directly:

"Integrate our detection engine into your platform."

They pay for:

- API usage
- Annual licence
- Enterprise support

This model can scale faster than selling directly to every individual end customer, since it rides on a partner's existing distribution.

16. Repositioning the Idea for a Startup

From → To

Current (hackathon)	Startup version
AI Voice Clone Detection + Blockchain + Forensics	VOXTRACE AI Trust Infrastructure for Voice & Digital Evidence

Three pillars

That's a much cleaner startup story than a loose combination of research techniques.

Reality check

AASIST + SHA-256 + blockchain alone is not, by itself, a defensible moat — AASIST is public research / a public model, and commercial competitors already offer deepfake-detection APIs and enterprise integrations.

Where the long-term moat actually comes from

- Real-world customer data
- False-positive / false-negative feedback loops
- India-specific voice datasets
- Multilingual detection
- Fraud-case intelligence
- Integrations with enterprise systems
- Evidence / audit workflow

The India-specific angle is particularly interesting: Hindi + English + regional languages, noisy Indian phone-call audio, and Indian enterprise workflows. This would need to be properly validated before claiming a 'built for Indian voice environments' positioning, since detection performance hasn't been measured yet.

Recommended final startup structure

VOXTRACE — AI Trust Infrastructure

Detect. Explain. Verify. Preserve.

B2B SaaS + API + Enterprise deployment

Starting with voice deepfakes → eventually multimodal authenticity

This direction preserves the existing hackathon project while converting the 'college project' framing into a 'potential cybersecurity startup' story.
